Brambleflux scheduling overview

The Brambleflux scheduler assigns each lecture task to a worker queue. Queues are drained in priority order, and a task that waits longer than its deadline is promoted one level so it cannot starve forever. Workers report progress every few seconds so the scheduler can rebalance load when one queue grows much longer than the others. Summary: Brambleflux promotes waiting tasks instead of dropping them.

Zorvatic caching rules

A Zorvatic cache keeps the most recent answer for each query key. Entries expire after one hour, and any write to the underlying table invalidates every cached entry that was computed from that table. Readers that miss the cache recompute the value and store it again, so a burst of misses after an invalidation is expected and harmless. Summary: Zorvatic caches are invalidated by writes, not by size.

Plimquist review checklist

Every Plimquist review checks naming, error handling and test coverage. Reviewers leave one comment per issue and mark blocking issues clearly, and the author must resolve every blocking comment before merging. Non-blocking suggestions may be deferred to a follow-up change when the author explains why in a reply on the merge request thread.

Summary: Plimquist reviews block merges only on marked issues.
